

Panel A: external calibration degrades on the small external sets (N=66, N=136), while the largest external set (N=984, ECE=0.044) remains close to calibrated; this pattern is consistent with internal-external distribution shift but is not by itself a causal test of shift. Post-hoc isotonic recalibration is unstable on the small sets due to sparse bins. Panel B: internal EC-stratified MCC (ESM2-150M); classes flagged as low-power exploratory (e.g. EC7) are shown with open markers and should not be over-interpreted.
